

### 3.9.2 Conversion of an NFA with $\varepsilon$ Moves to DFA without $\varepsilon$ Move

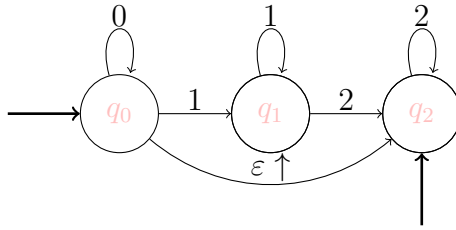

Let us assume that in the NFA we want to remove the  $\varepsilon$  move which exists between the states  $S_1$  and  $S_2$ .

This can be removed in the following way

- Find all the edges (transitions) those start from the state  $S_2$ .
- Duplicate all these transitions starting from the state  $S_1$ , keeping the edge label the same.
- If  $S_1$  is the initial state, also make  $S_2$  as the initial state.
- If  $S_2$  is the final state, also make  $S_1$  as the final state.

Consider the following examples.

**Example 3.8** Convert the following NFA with null move in Fig. 3.13 to an equivalent DFA without  $\varepsilon$  move.

**Fig. 3.13**

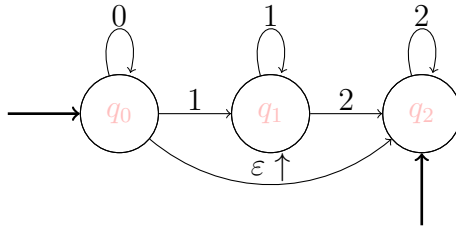

**Solution:** Three null moves exist in the previous transitional diagram. The transitions are

1. from  $q_0$  to  $q_1$
2. from  $q_1$  to  $q_2$
3. from  $q_0$  to  $q_2$

These null transitions are removed step by step.

**Step I:**

1. Between the states  $q_0$  and  $q_1$ , there is a null move. If we want to remove that null transition, we have to find all the edges starting from  $q_1$ . The edges are  $q_1$  to  $q_1$  for input 1 and  $q_1$  to  $q_2$  for input  $\varepsilon$ .
2. All these transitions starting from the state  $q_0$  are duplicated, keeping the edge label the same.  $q_0$  is the initial state, so make  $q_1$  also an initial state. The modified transitional diagram is given in Fig. 3.14.

**Fig. 3.14**

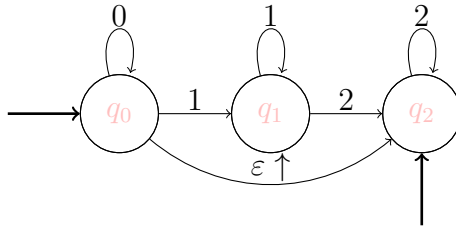

**Step II:**

Between  $q_1$  and  $q_2$ , there is a null transaction. To remove that null transition, find all the edges starting from  $q_2$ . The edge is  $q_2$  to  $q_2$  for input 2.

**Conversion of an NFA with  $\varepsilon$  Moves to DFA without  $\varepsilon$  Move**

**62** | Introduction to Automata Theory, Formal Languages and Computation

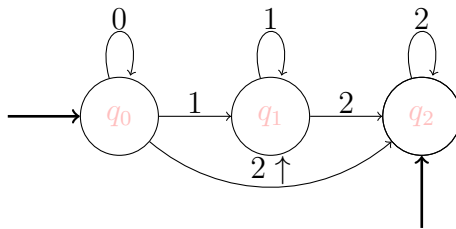

2. Duplicate the transition starting from the state  $q_1$ , keeping the edge label the same.  $q_1$  is the initial state, so make  $q_2$  also an initial state.  $q_2$  is the final state, so make  $q_1$  also a final state. The modified transitional diagram is given in Fig. 3.15.

**Fig. 3.15**

**Step III:**

1. Between  $q_0$  and  $q_2$ , there is a null transaction. To remove that null transition, find all the edges starting from  $q_2$ . The edge is  $q_2$  to  $q_2$  for input 2.
2. Duplicate the transition starting from the state  $q_0$ , keeping the edge label the same.  $q_0$  is the initial state, so make  $q_2$  also an initial state.  $q_2$  is the final state, so make  $q_0$  also a final state. The modified transitional diagram is given in Fig. 3.16.

**Fig. 3.16**

This is the equivalent NFA without  $\varepsilon$  move obtained from the NFA with null transaction.

**Example 3.9** Convert the following NFA with null move to an equivalent NFA without  $\varepsilon$  move as given in Fig. 3.17.

## 1 picture

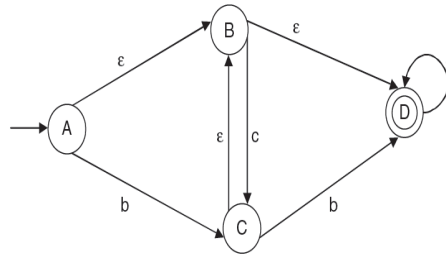

Fig.3.17

**Solution:** In the given NFA with  $\varepsilon$  move, there are three  $\varepsilon$  transitions: from  $A$  to  $B$ , from  $B$  to  $D$ , and from  $B$  to  $C$ . The three  $\varepsilon$  transitions are removed step by step.

**Step I:** There is a  $\varepsilon$  transition from  $A$  to  $B$ . To remove that  $\varepsilon$  transition, we have to find all the edges starting from  $B$ . The edges are  $B$  to  $C$  for input  $c$  and  $B$  to  $D$  for input  $\varepsilon$ .

Duplicate the transition starting from the state  $A$ , keeping the edge label the same.  $A$  is the initial state, so make  $B$  also an initial state. The modified transaction diagram is shown in Fig. 3.18.

## 2 picture

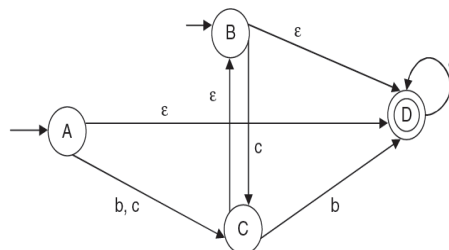

Fig.3.18

**Step II:** Again there are three  $\varepsilon$  transactions in the NFA. These are from  $A$  to  $D$ , from  $B$  to  $D$ , and from  $C$  to  $B$ . Let us remove the  $\varepsilon$  transaction from  $B$  to  $D$ . The edge starting from  $D$  is  $D$  to  $D$  for input  $a$ . Duplicate the transition starting from the state  $B$ , keeping the edge label the same. As  $B$  is the initial state,  $D$  will also be the initial state. As  $D$  is the final state,  $B$  will also be the final state. The modified transaction diagram will be as shown in Fig. 3.19.

### 3 picture

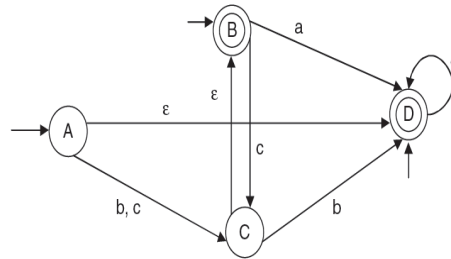

Fig. 3.19

**Step III:** Now we are going to remove the  $\varepsilon$  transaction from  $A$  to  $D$ . The edge starting from  $D$  is  $D$  to  $D$  for input  $a$ . Duplicate the transition starting from the state  $A$ , keeping the edge label the same. As  $A$  is the initial state,  $D$  will also be the initial state. As  $D$  is the final state,  $A$  will also be the final state. The modified transaction diagram will be as shown in Fig. 3.20.

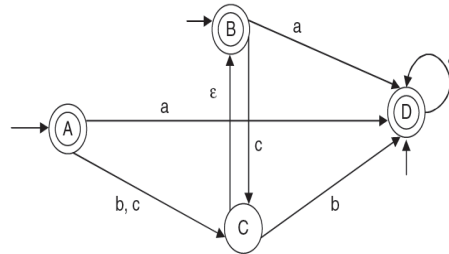

Fig. 3.20

## Equivalence of DFA and NFA

64 | Introduction to Automata Theory, Formal Languages and Computation

**Step IV:** There is only one  $\varepsilon$  transaction from  $C$  to  $B$ . To remove this, find the edges starting from  $B$ .

There are two: from  $B$  to  $D$  for input  $a$  and from  $B$  to  $C$  for input  $c$ . Start these edges from  $C$ .  $B$  is the final state, so make  $C$  as the final state. The modified transitional diagram will be as shown in Fig. 3.21.

This is the equivalent NFA without  $\varepsilon$  move obtained from the NFA with null transaction.

### 3.10 Equivalence of DFA and NFA

A DFA can simulate the behaviour of an NFA by increasing its number of states. The DFA does not contain any null move and any transitional functions of a state and input reaching to more than one states. In this section, we shall prove the following: ‘If a language  $L$  is accepted by an NDFA, then there exists a DFA that accepts  $L$ ’.

*Proof* : Let  $M$  be an NDFA denoted by  $\{Q, \Sigma, \delta, q_0, F\}$  which accepts  $L$ .

We construct a DFA  $M' = \{Q', \Sigma, \delta', q'_0, F'\}$ , where  $Q'$  contains the subsets of  $Q$ , i.e.,  $Q' = 2^Q$ .

$Q'$  may be denoted by  $[q_1, q_2, \dots, q_n]$  as a single state where  $q_1, q_2, \dots, q_n \in Q$

Initial state  $q'_0 = [q_0]$

Final state  $F' =$  set of all states in  $Q'$  containing at least one final state of  $M$ .

Transitional function  $\delta'$  is defined as

$$\delta'([q_1, q_2, \dots, q_n], a) = [P_1, P_2, \dots, P_k] \text{ where } q_1, q_2, \dots, q_n \in Q, a \in \Sigma$$

and

$$\begin{aligned} \delta'(\{q_1, q_2, \dots, q_n\}, a) &= \delta(q_1, a) \cup \delta(q_2, a) \cup \dots \cup \delta(q_n, a) \\ &= P_1 \cup P_2 \cup \dots \cup P_k \end{aligned}$$

This is the case for a single input 'a'. Now, we shall prove it for some input string  $x$ .  $x$  may be of length 0 to length  $n$ . We prove this by induction.

Let  $|x| = 0$ , i.e.,  $x$  is a null string.

$$\delta'(q'_0, x) = [q_0] \text{ as } q'_0 = [q_0] \text{ and } \delta(q_0, \varepsilon) = q_0.$$

Thus, the induction has a base condition.

Let us assume that it is true for each string of length  $n$ . Now we need to prove that the result is true for any string of length  $(n + 1)$ .

Let  $S = xa$ .

So,  $|S| = |xa| = |x| + |a| = n + 1$ .

$$\delta'(q'_0, S) = \delta'(q'_0, xa) = \delta'(\delta'(q'_0, x)a).$$
